DESCRIPTION

The ST75C185 is low power BICMOS device containing three independent drivers and five receivers that is used to interface data terminal equipment (DTE) with data circuit-terminating equipment (DCE). This device has been designed to conform to Standards ANSI/EIA-232-E. The drivers have a controlled output slew rate that is limited to a maximum of 30V/ μ s and the receivers have filters that reject input noise pulses that are shorter than 1 μ s. Both

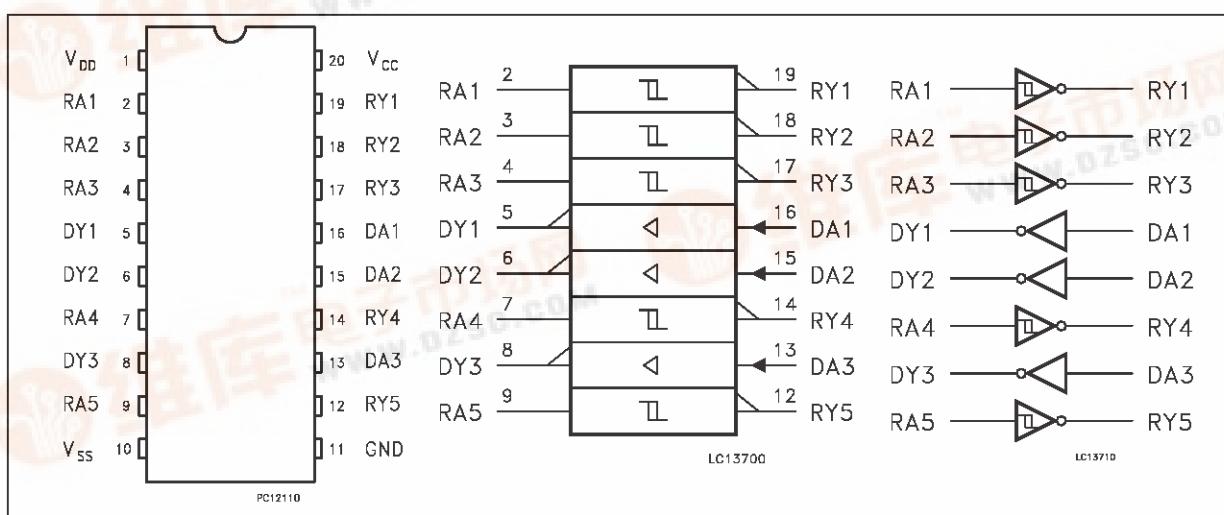

these features eliminate the need of external components.

The ST75C185 hasn't a power sequence fault condition. It has been designed using low-power techniques in a BICMOS technology.

In most application the receivers contained in this device will interface to single inputs peripheral devices such as ACEs, UARTs or microprocessors. By using sampling, such peripheral devices are usually insensitive to the transition times of the input signals. If this is not the case, or for other uses, it is recommended that the ST75C185 receiver outputs be buffered by single gates of the HCMOS, ALS or 74F logic families.

APPLICATION INFORMATION: DIODES ON POWER SUPPLY

Diodes placed in series with the V_{DD} and V_{SS} leads protect the ST75C185 in the fault condition in which the devices output are shorted to $\pm 15V$ and the power supplies are at low state and provide low-impedance path to ground (see Figure below). Any idle transmitter input must be connected to GND or V_{CC} . This device is not sensitive to power supply sequence.
