

# Am25L02/25L03/25L04

Low-Power, Eight-Bit/Twelve-Bit Successive Approximation Registers

## Distinctive Characteristics

- Contains all the storage and control for successive approximation A-to-D converters.
- Can be operated in START-STOP or continuous conversion mode.
- 100% reliability assurance testing in compliance with MIL-STD-883.
- Can be used as serial-to-parallel converter or ring counters.

## FUNCTIONAL DESCRIPTION

The Am25L02, Am25L03 and Am25L04 are 8-bit and 12-bit TTL Successive Approximation Registers. The registers contain all the digital control and storage necessary for successive approximation analog-to-digital conversion. They can also be used in digital systems as the control and storage element in recursive digital routines.

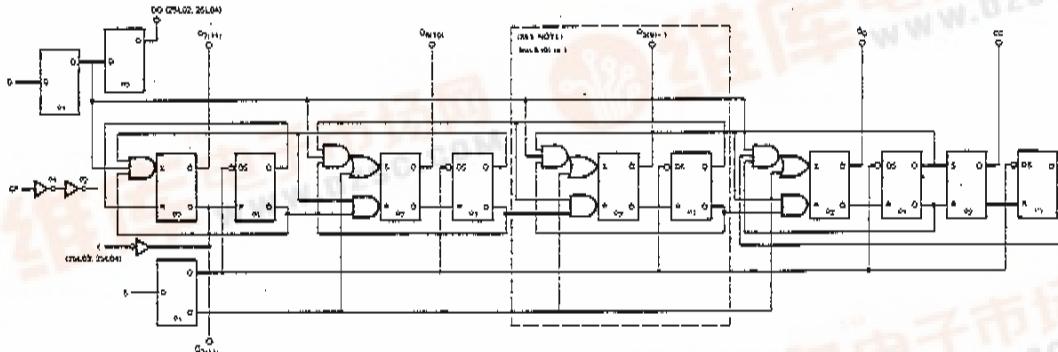

The registers consist of a set of master latches that act as the control elements in the device and change state when the input clock is LOW, and a set of slave latches that hold the register data and change on the input clock LOW-to-HIGH transition. Externally the device acts as a special purpose serial-to-parallel converter that accepts data at the D input of the register and sends the data to the appropriate slave latch to appear at the register output and the DO output on the Am25L02 and Am25L04 when the clock goes from LOW-to-HIGH. There are no restrictions on the data input; it can change state at any time except during the set-up time just prior to the clock transition. At the same time that data enters the register bit the next less significant bit is set to a LOW ready for the next iteration.

The register is reset by holding the S (Start) signal LOW during the clock LOW-to-HIGH transition. The register synchronously resets to the state Q7(11) LOW, (Note 2) and all the remaining register outputs HIGH. The CC (Conversion Complete) signal is also set HIGH at this time. The S signal should not be brought back HIGH until after the clock LOW-to-HIGH transition in order to guarantee correct resetting.

After the clock has gone HIGH resetting the register, the S signal is removed. On the next clock LOW-to-HIGH transition the data on the D input is set into the Q7(11) register bit and the Q6(10) register bit is set to a LOW ready for the next clock cycle. On the next clock LOW-to-HIGH transition data enters the Q6(10) register bit and Q5(9) is set to a LOW. This operation is repeated for each register bit in turn until the register has been filled. When the data goes into Q0, the CC signal goes LOW, and the register is inhibited from further change until reset by a Start signal.

In order to allow complementary conversion the complementary output of the most significant register bit is made available. An active LOW enable input, E, on the Am25L03 and Am25L04 allows devices to be connected together to form a longer register by connecting the clock, D, and S inputs together and connecting the CC output of one device to the E input of the next less significant device. When the Start signal resets the register, the E signal goes HIGH, forcing the Q7(11) bit HIGH and inhibiting the device from accepting data until the previous device is full and its CC goes LOW. If only one device is used the E input should be held at a LOW logic level (Ground). For continuous conversion the CC output is connected to the S input so that the device automatically restarts at the end of a conversion. If all the bits are not required, the register may be truncated and conversion time saved by using a register output going LOW rather than the CC signal to indicate the end of conversion.

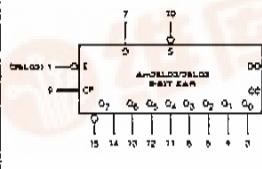

## LOGIC DIAGRAMS

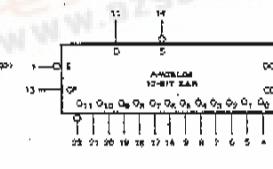

Notes: 1. Cell logic is repeated for register stages, Q5 to Q1 Am25L02/3, Q9 to Q1 Am25L04.  
2. Numbers in parentheses are for Am25L04.

	X	X	H	X	H	NC	NC	NC						

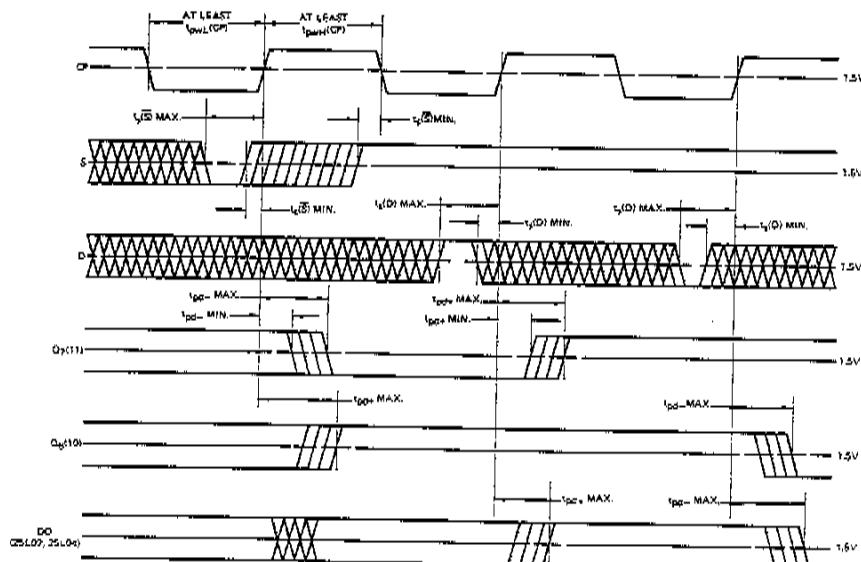

H = HIGH Voltage Level  
 L = LOW Voltage Level  
 X = Don't Care  
 NC = No Change

Note: Truth Table for Am25L04 is extended to include 12 outputs.

### USER NOTES FOR A/D CONVERSION

- The register can be used with either current switches that require a low voltage level to turn the switch on, or current switches that require a high voltage level to turn the current switch on. If current switches are used which turn on with a low logic level the resulting digital output from the register is active LOW. That is, a logic "1" is represented as a low voltage level. If current switches are used that turn on with a high logic level then the digital output is active HIGH; a logic "1" is represented as a high voltage level.
- For a maximum digital error of  $\pm \frac{1}{2}$  LSB the comparator must be biased. If current switches that require a low voltage level to turn on are used, the comparator should be biased  $+\frac{1}{2}$  LSB and if the current switches require a high logic level to turn on then the comparator must be biased  $-\frac{1}{2}$  LSB.
- The register, by suitable selection of resistor ladder network, can be used to perform either binary or BCD conversion.
- The register can be used to perform 2's complement conversion by offsetting the comparator  $\frac{1}{2}$  full range  $\pm \frac{1}{2}$  LSB and using the complement of the MSB  $Q_7$  (11) as the sign bit.
- If the register is truncated and operated in the continuous conversion mode a lock-up condition may occur on power-on. This situation can be overcome by making the START input the OR function of CC and the appropriate register output.

Am25L02/3/4 APPLICATION  
Continuous Conversion Analog-to-Digital Converter

LIC-242

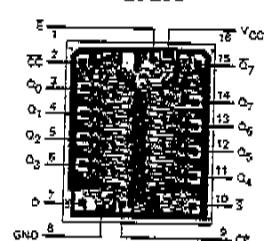

This shows how the Am25L02/3/4 registers are used with a Digital-to-Analog converter and a comparator to form a very high-speed continuous conversion Analog-to-Digital converter. Conversion time is limited mainly by the speed of the D/A converter and comparator with typical conversion rates of 300,000 conversions per second. The comparator can be the Am111 precision comparator, or Am106 high-speed comparator.
